FlowOpt: Bridging the Gap Between Optimization Technology and Manufacturing Planners

Roman Barták¹, Milan Jaška¹, Ladislav Novák¹, Vladimír Rovenský¹, Tomáš Skalický¹, Martin Cully², Con Sheahan², Dang Thanh-Tung²

Abstract. FlowOpt is an integrated collection of tools for optimization in production environments. It was workflow developed as a demonstration of advancements in the areas of modeling and optimization with the focus on simplifying the usage of the technology for end customers. The system consists of several interconnected modules. First, the user visually models a workflow describing the production of some item. Then the user specifies which items and how many of them should be produced (order management) and the system automatically generates a production schedule. This schedule is then visualized in the form of a Gantt chart where the user can arbitrarily modify the schedule. Finally, the system can analyze the schedule and suggest some improvements such as buying a new machine. Constraint satisfaction technology is the solving engine behind these modules.

1 INTRODUCTION

One of the biggest problems of today's advanced technology is its limited accessibility to users working in a given domain but not necessarily being experts in the used technology. Apple's iPhone is a great example how advanced technology can be made accessible to regular users. With the tradeoff of slightly limited functionality, it provides user interface to very advanced techniques such as Q&A (question and answering) that anyone can immediately use without the hassle of long training.

FlowOpt is a system that attempts to address the above problem and bridges the gap between advanced optimization technology developed at universities and practitioners from production planning. In particular FlowOpt is targeted to production planning in Small and Medium Enterprises. It covers modeling, optimizing, visualizing, and analyzing production processes in a streamlined feature-rich environment. FlowOpt is a student software project at Charles University in Prague (Czech Republic). The software itself is a collection of closely interconnected modules that can be plugged into the enterprise performance optimization system MAK€ from Entellexi Ltd. (Ireland).

2 FLOWOPT FUNCTIONALITY

FlowOpt covers almost the complete production-planning cycle. It allows users to describe visually and interactively the process of producing any item in the form of a nested workflow with alternatives. After specifying what and how many items should be produced, the system generates a production plan taking in account the limited resources in the factory. The plan is visualized in the form of a Gantt view that uses information about workflows and allows users to arbitrarily modify the plan by selecting alternative processes or allocating activities to different times or resources. Finally, the schedule can be analyzed, the bottleneck parts are highlighted and some improvements are suggested to the user. We will now introduce the functionality of individual modules.

Workflow Editor allows users to create and modify workflows in a visual way. We use the concept of nested workflows that are built by decomposing the top task until the primitive tasks are obtained. Three types of decompositions are supported: either the task is decomposed into a sequence of sub-tasks which forms a *serial decomposition* or the task is decomposed into a set of subtasks that can run in parallel – a *parallel decomposition* – or finally, the task is decomposed into a set of alternative sub-tasks such that exactly one sub-task will be processed to realize the top task – an *alternative decomposition* (Figure 1). The final primitive

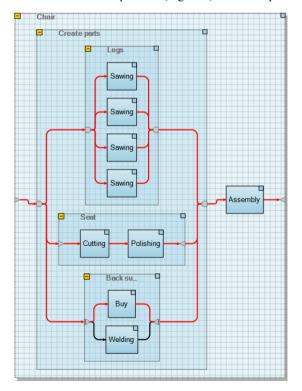

Figure 1. Visualization of nested workflow in the FlowOpt Workflow Editor (from top to down there are parallel, serial, and alternative decompositions)

tasks are then filled with activities defined in the MAK€ system; each activity has a given duration and a set of resources necessary for its processing. The workflow can be built in the top-down way by decomposing the tasks or in the bottom-up way by composing the tasks; both approaches can be used together as the user prefers. In addition to the core nested structure, the user can also specify extra binary constraints between the tasks such as precedence relations, temporal synchronizations, or causal relations. Everything is done using an intuitive drag-and-drop approach. The system also supports import of foreign workflows and it has the function of fully automated verification of workflows.

When the workflows for all items are defined, this is the modeling stage, it is possible to generate production plans. This is as easy as selecting the required items (workflows) in the **Order Manager**, specifying their quantities and required delivery date and starting the **Optimizer** by pressing a single button in GUI. The data about workflows, activities, and resources are automatically converted to the scheduling model and the system produces a schedule that is a selection of activities (tasks) from the workflows (if there are alternatives) and their allocation to time and resources. The Optimizer attempts to optimize both earliness and lateness costs that are derived from the delivery dates.

The generated schedule (production plan) can by visualized in the **Gantt Viewer**. This module provides both traditional views of the schedule, namely the task-oriented and resource-oriented views. Because the Gantt Viewer has full access to the workflow specification, it can also visualize the alternatives that were not selected by the Optimizer. The Gantt Viewer allows users to modify any aspect of the production plan using the drag-and-drop techniques. The user can move activities to different times and resources and change their duration. It is even possible to select another alternative than that one suggested by the Optimizer. Because the Gantt Viewer is aware about all the constraints originating from the workflow specification, it can also highlight violation of any of these constraints. Even more, the Gantt Viewer can automatically repair the flaws that were introduced to the schedule by the user's modifications.

The final module is an **Analyzer** that is responsible for suggesting improvements of the production process. The Analyzer first finds bottlenecks in a given schedule, for example an overloaded resource. For each bottleneck, the analyzer suggests how to resolve it – this could be by buying a new resource or by decreasing the duration of certain activities (for example by staff training). Each such improvement is evaluated by the Optimizer. Finally the system selects a set of improvements such that their combination brings the best overall improvement of the production process under the given constraints such as a limited budged to realize the improvements.

3 TECHNOLOGY INSIDE

The FlowOpt system is a unique combination of modeling and optimization techniques. It is built around the concept of Nested Temporal Networks with Alternatives [2] that were suggested as a model of production workflows with a hierarchical structure and alternative processes. In FlowOpt this concept was slightly modified and extended with additional constraints. These constraints may introduce flaws to the nested structure (for example a cycle) and hence novel verification techniques for workflows were proposed and implemented. The general verification technique is based on modeling the problem as a constraint satisfaction problem and using advanced temporal reasoning techniques, namely IFPC algorithm [5] to validate that there exists a feasible process for each task in the workflow. The information about workflows is combined with data about activities and resources to automatically build a scheduling model [3]. Again, we use constraint satisfaction techniques to solve the scheduling problem; in particular, ILOG CP Optimizer is used to generate optimal schedules [4]. The schedule is visualized in the form of a Gantt chart where the user can modify it. The viewer highlights constraints violated by user intervention, but it can also automatically repair these constraints using a technique of shifting activities locally in time [1]. Again, constraint satisfaction techniques and IFPC algorithm [5] are used in background. Finally, the Analyzer uses the ideas of critical path to discover weak parts of the schedule. Currently it uses ad-hoc rules to suggest some improvements (an overloaded resource \rightarrow buy a new resource). The improvements are then applied to the scheduling model and the Optimizer generates a new schedule whose cost is used to evaluate the improvement. Some interactions between the possible improvements are also discovered during this process. From the set of possible improvements, a subset with the best overall cost is selected by using the techniques of project portfolio optimization. Again, the problem is modeled as a constraint satisfaction problem and ILOG CP Optimizer is used to solve it.

4 DEMONSTRATION DESCRIPTION

The complete process of generating a production plan will be demonstrated. First, the design process of modeling nested workflows will be presented including the demonstration of workflow verification and its outputs. The schedule will be generated in real time and then the visualization capabilities of the Gantt Viewer will be demonstrated. We will show how the schedule can be modified and how the system can automatically repair the violated constraints.

ACKNOWLEDGEMENTS

The research and development is supported by the Czech Science Foundation under the contract P202/10/1188.
